Assessing injury on GOM cetaceans

August 11, 2022

Preamble

This is an Electronic Supplement to the manuscript Marques et al. "Quantifying Deepwater Horizon oil spill induced injury on pelagic cetaceans" submitted to Marine Ecology Progress Series (MEPS).

There are 7 Electronic Supplements to the paper. The master file containing links to all the other 6 additional Electronic Supplements related to this paper is ESO_ElectronicSupplements.

You might be reading this file as a pdf or as an html. The links on this file only work if you are using the html version of it, available via the github repository or if you compiled it yourself as html and you have all the 7 html files in the same folder. Otherwise, as a pdf distributed as an Electronic Supplement to the MEPS paper, the links might not work. They might work. If it is possible, we can work with the MEPS Editorial Office such that we can add links below that will link to actual files, say the pdfs of each of these 7 files, on the publisher server.

Version history

This section details the version history for static pdf files submitted as Electronic Supplement pdfs:

• 1.0 [12 Aug 2022] Version included as a pdf Electronic Supplement in the MEPS original submission

Introduction

In this document we present the results of the age, sex and class structured model implemented for all species/stock in the GOM.

We report here the injury metrics originally considered in Schwacke et al. (2017): (1) lost cetacean years (LCY), the difference between the baseline and injured population sizes, summed over the entire modeled time period; (2) years to recovery (YTR), the number of years required before the injured population trajectory reaches 95% of the baseline population trajectory; and (3) maximum proportional decrease (MPD), the difference between the two population trajectories when the injured trajectory is at its lowest point, divided by the baseline. Note that LCY is intuitively the metric that is most dependent on initial population size.

Running the simulations

The code below runs the simulations for all species, and stores the results in appropriate files, stored in appropriate species specific folders.

This code is included for completeness and does not need to be run as part of compiling this dynamic report as the results are already available in relevant files and it takes a considerably log time to run.

Creating objects to hold summary results:

The taxonomic units and the corresponding codes considered in this document are:

- Bwsp beaked whales, Beaked whales spp
- Fatt pygmy killer whale, Feresa attenuata
- Ggri Risso's dolphin, Grampus griseus

- Gmac short-finned pilot whale, Globicephala macrorhynchus
- Kosp Kogia species, Kogia sp.
- Pele melon-headed whale, Peponocephala electra
- Pmac sperm whale, Physeter macrocephalus
- Satt pantropical spotted dolphin, Stenella attenuata
- Sbre rough-toothed dolphin, Steno bredanensis
- Scly Clymene dolphin, Stenella clymene
- Scoe striped dolphin, Stenella coeruleoalba
- Sfro Atlantic spotted dolphin, Stenella frontalis
- Slon spinner dolphin, Stenella longirostris
- Ttro offshore bottlenose dolphins, Tursiops truncatus
- Ttrs shelf bottlenose dolphins, Tursiops truncatus

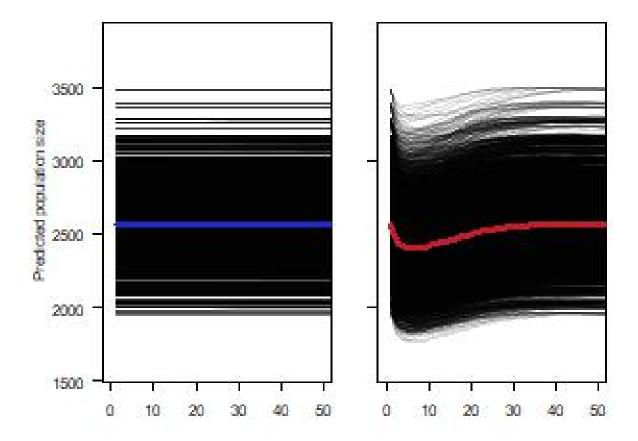

We re-order the results tables upfront so that results are organized by alphabetical order of the 4 letter code used to describe the taxonomic unit (this is also the order that the species are reported in tables 1 to 3 of the offshore paper).

The data for initial population sizes and proportion exposed are imported from a txt file produced inside ES2 ElectronicSupplements.

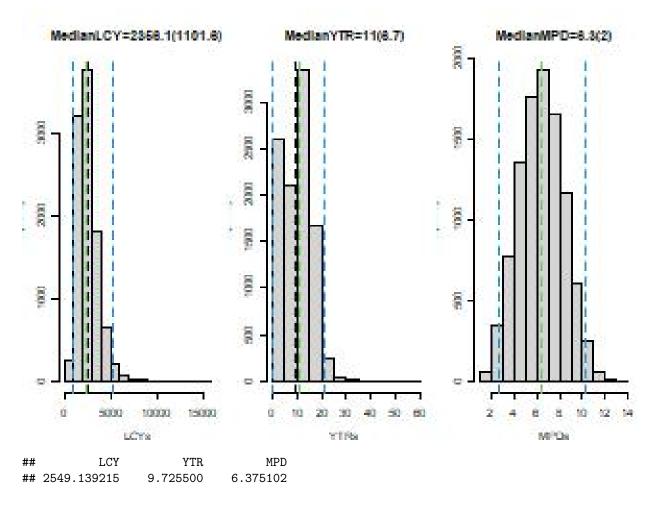

Results by species

We represent in turn, for each species, the simulated population trajectories under the oil spill and under the baseline scenarios, as well as the histograms of the distributions of the 3 injury metrics for each species.

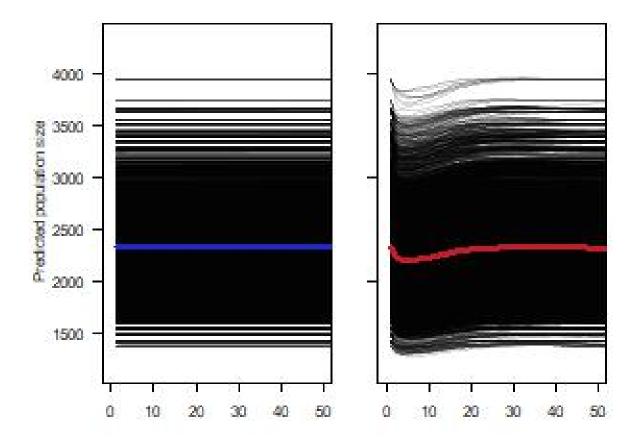

Physeter macrocephalus (Pmac, sperm whale)

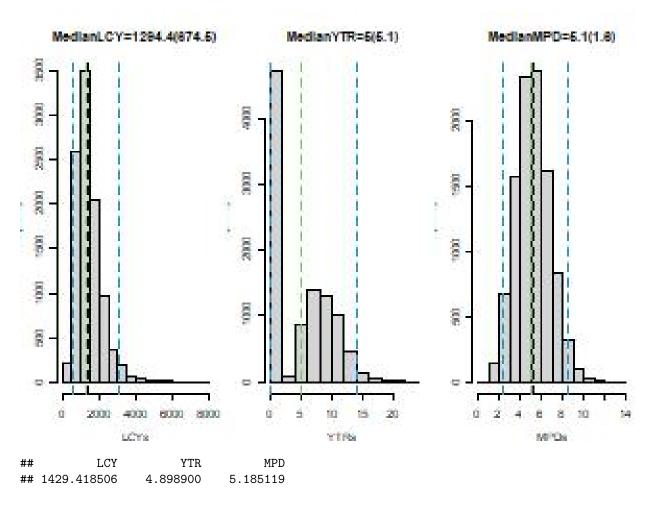

Mean for each of the injury metrics

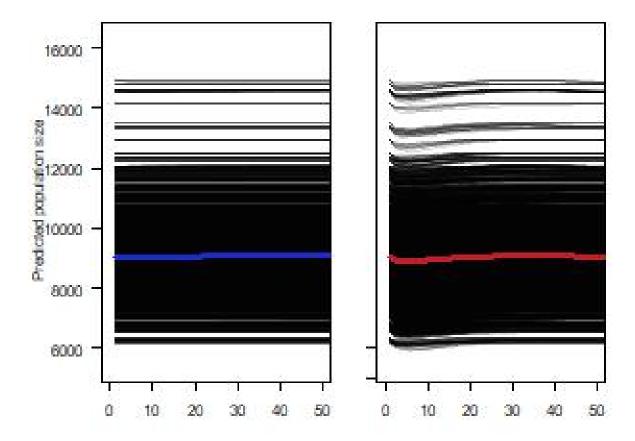

Kogia sp. (Kosp, kogia)

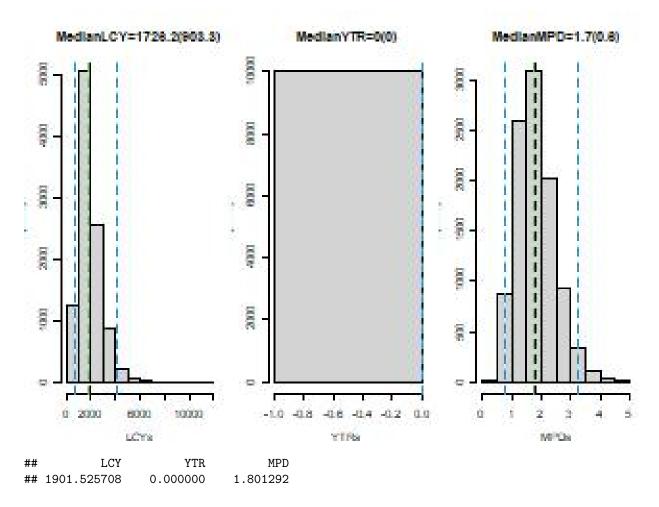

Mean for each of the injury metrics

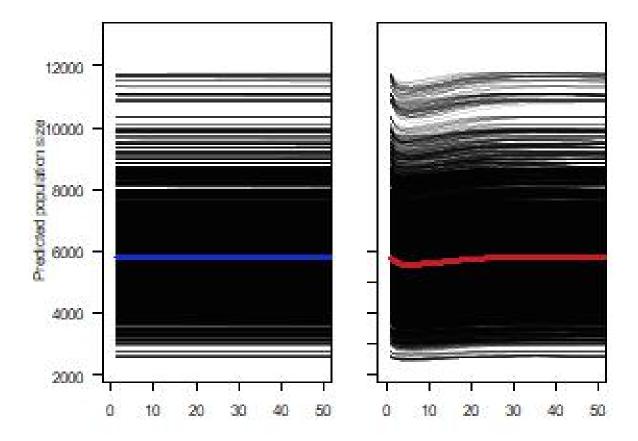

Stenella clymene (Scly, Clymene dolphin)

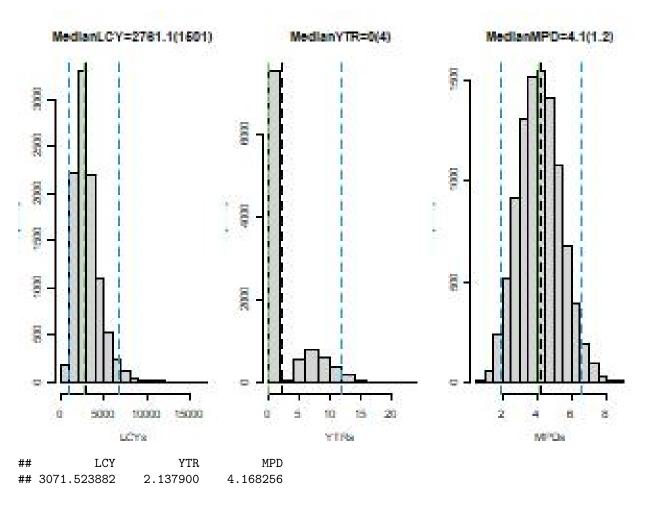

Mean for each of the injury metrics

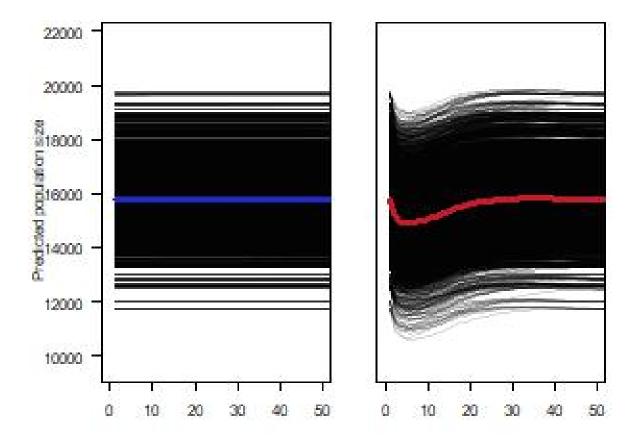

Peponocephala electra (Pele, melon-headed whale)

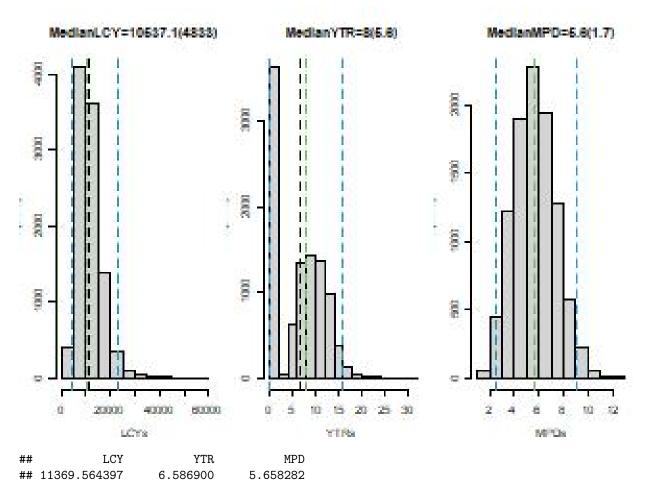

Mean for each of the injury metrics

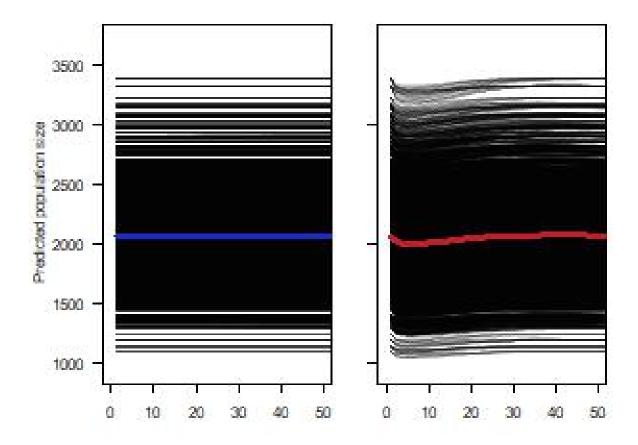

Tursiops truncatus (Ttro, offshore bottlenose dolphin)

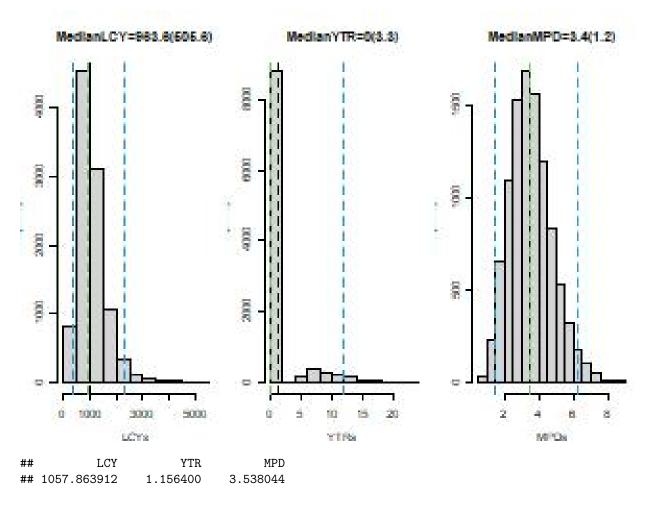

Mean for each of the injury metrics

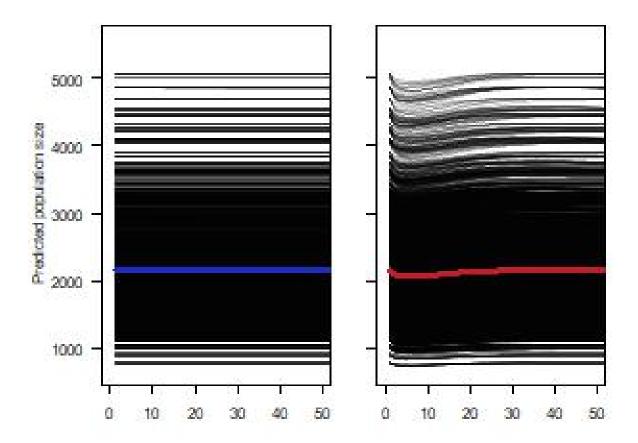

Globicephala macrorhynchus (Gmac, short finned pilot whale)

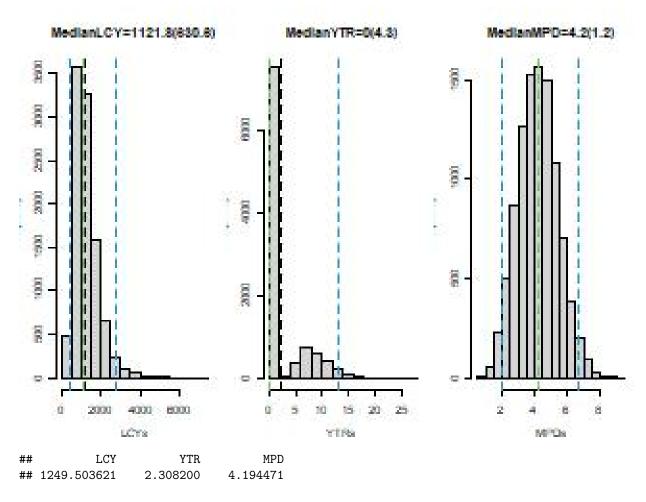

Mean for each of the injury metrics

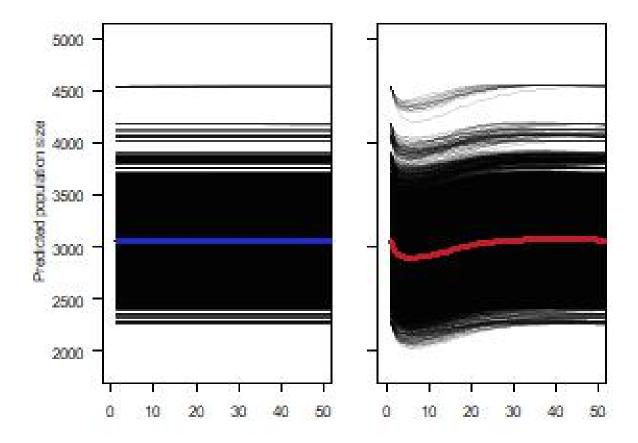

Feresa attenuata (Fatt, pygmy killer whale)

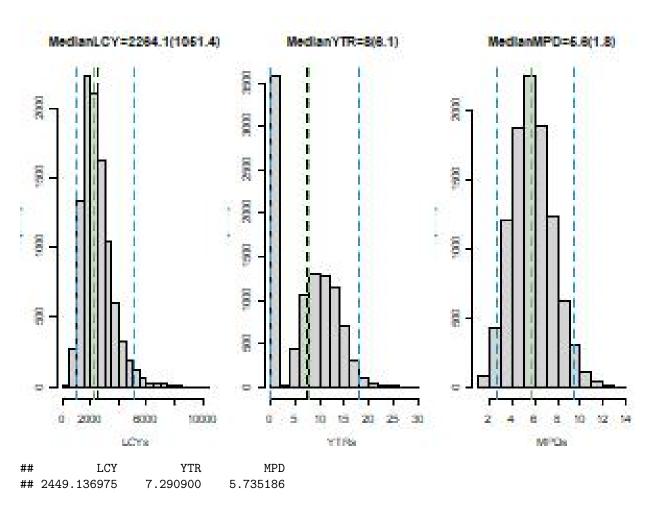

Mean for each of the injury metrics

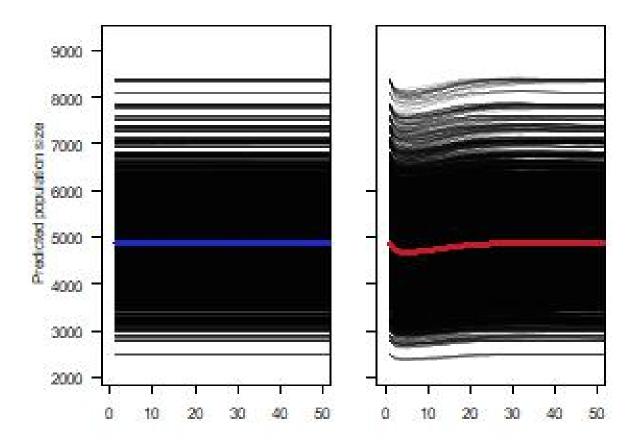

Grampus griseus (Ggri, Risso's dolphin)

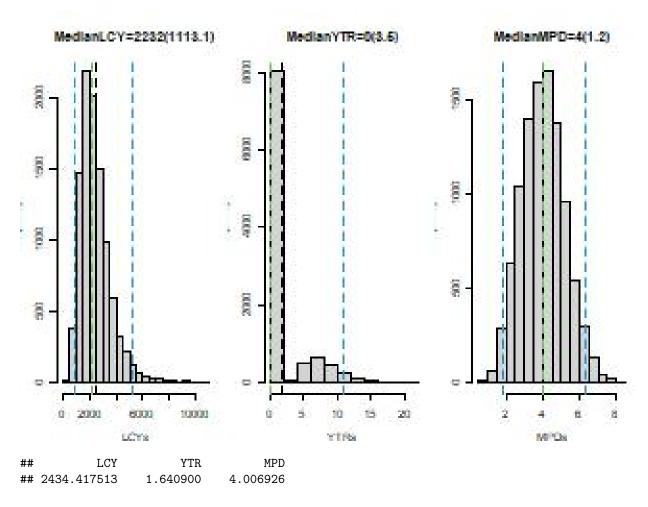

Mean for each of the injury metrics

 $Steno\ bredanensis\ ({\bf Sbre},\ {\bf rough-toothed\ dolphin})$

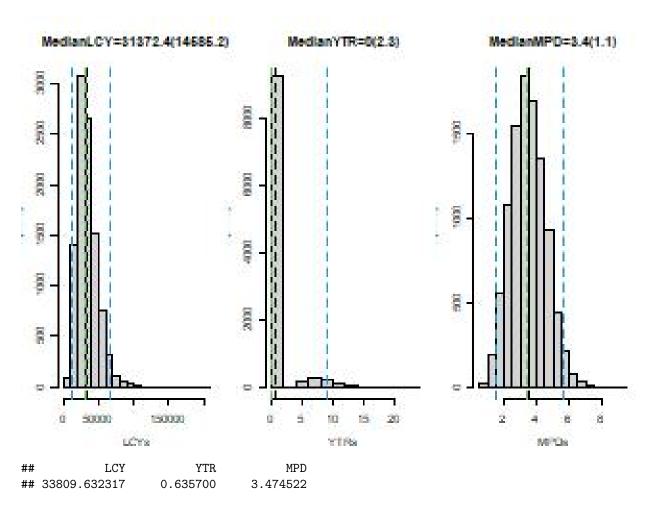

Mean for each of the injury metrics

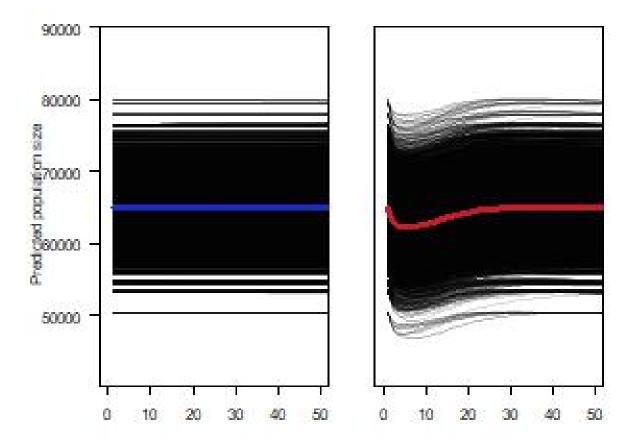

Stenella attenuata (Satt, pantropical spotted dolphin)

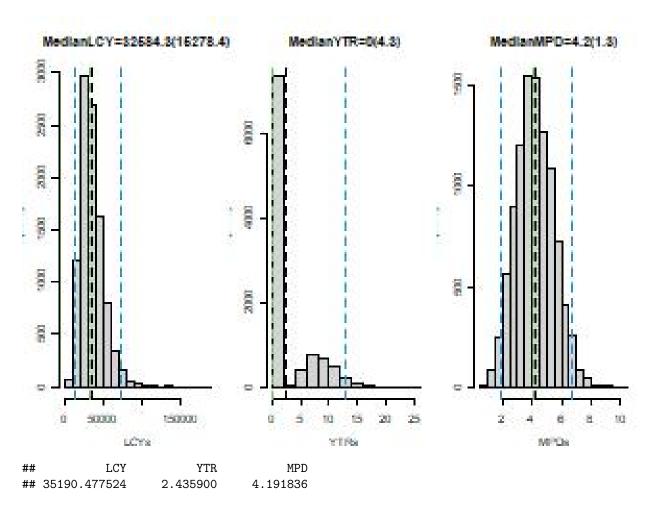

Mean for each of the injury metrics

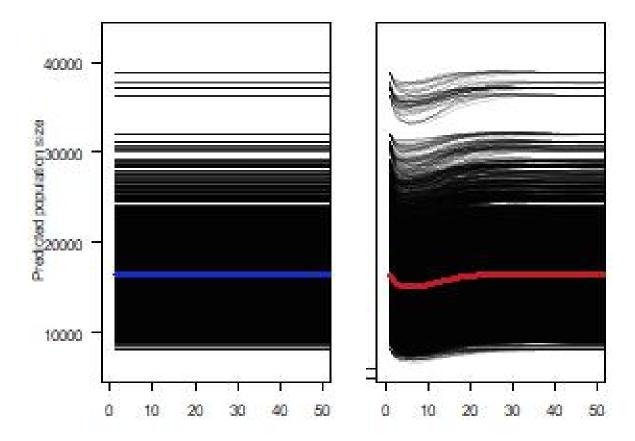

Tursiops truncatus (Ttrs, shelf bottlenose dolphin)

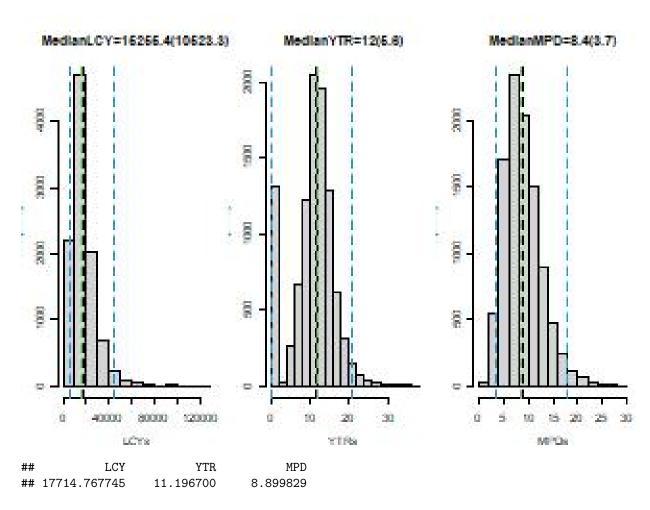

Mean for each of the injury metrics

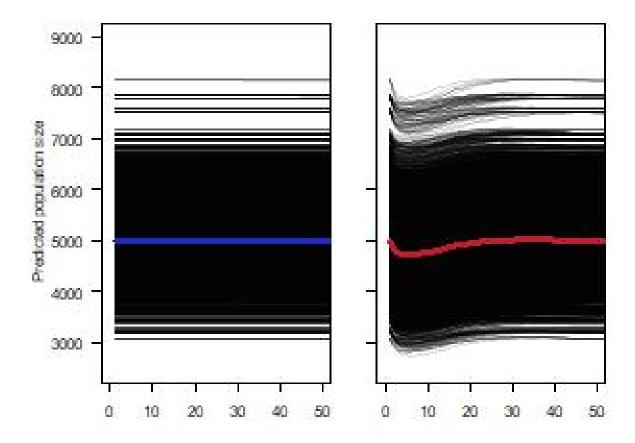

Stenella longirostris (Slon, spinner dolphin)

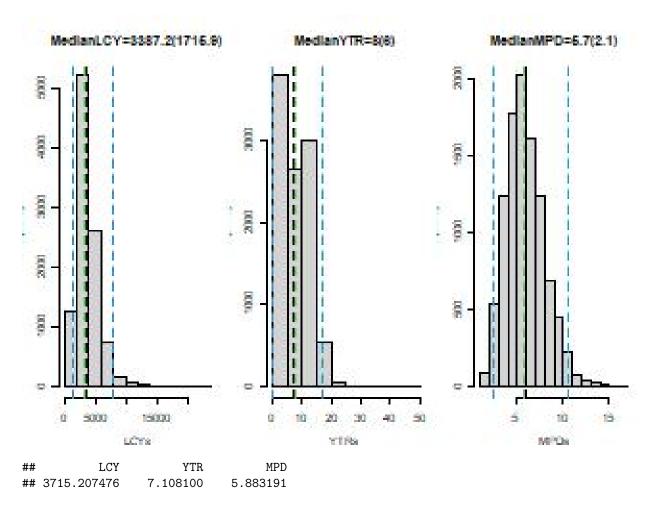

Mean for each of the injury metrics

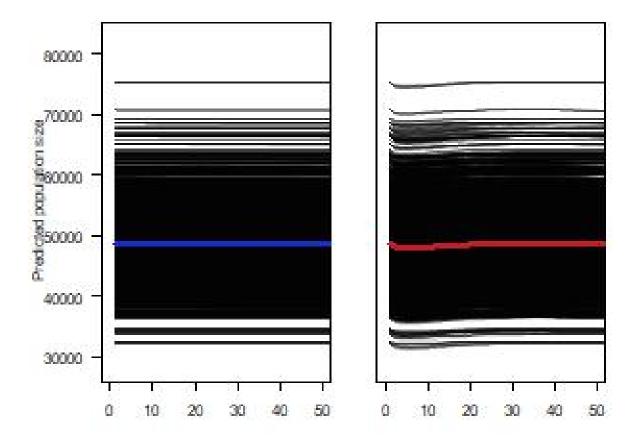

Stenella coeruleoalba (Scoe, striped dolphin)

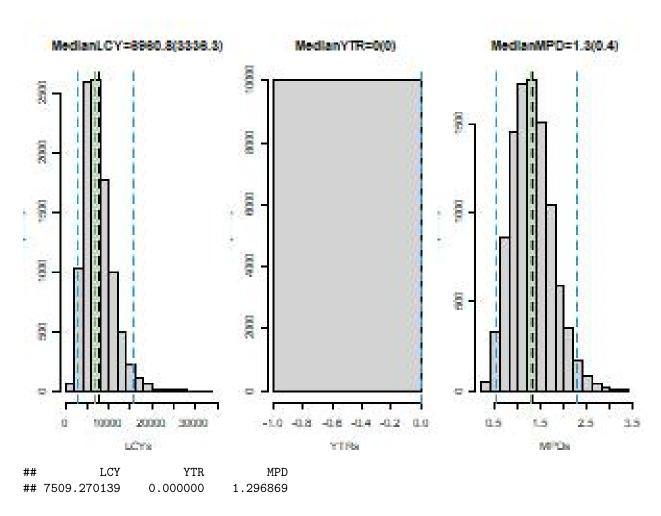

Mean for each of the injury metrics

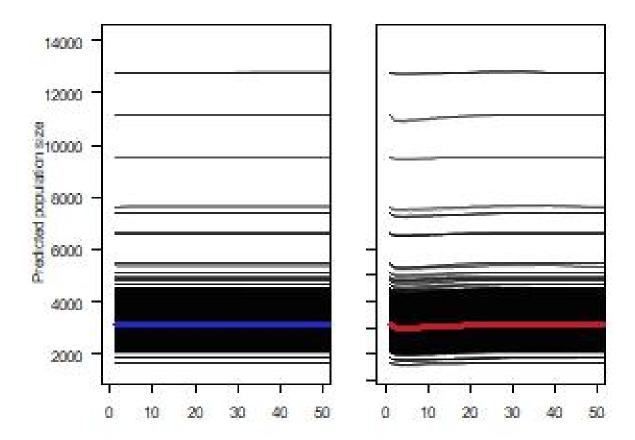

Stenella frontalis (Sfro, Atlantic spotted dolphin)

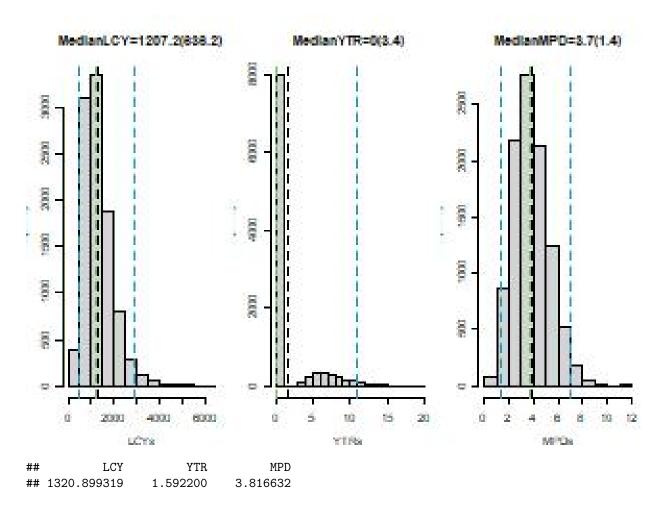

Mean for each of the injury metrics

Beaked whales spp (Bwsp)

Mean for each of the injury metrics

Comparisons across species

In this section we present some summary analysis of the results across the 15 taxonomic units considered.

Initial population and proportion exposed

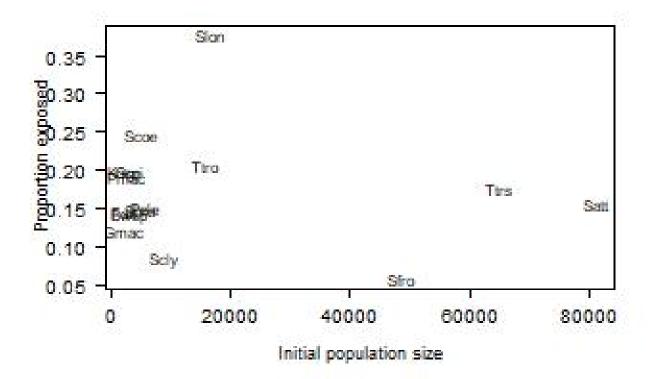

The population size and the proportion exposed are apriori expected to be key determinants of injury, since the population size will have a direct impact on LCY and the proportion exposed should have a direct impact on all 3 measures.

Table 1: Initial population size (N) and proportion exposed (Pexp) for the different stocks considered.

Sp	Nstart	Pexp		
Bwsp	3098	0.140		
Fatt	2152	0.145		
Ggri	3063	0.197		
Gmac	2065	0.120		
Kosp	2322	0.197		
Pele	5784	0.152		
Pmac	2561	0.191		
Satt	81233	0.155		
Sbre	4867	0.148		

Sp	Nstart	Pexp
Scly	9065	0.082
Scoe	5011	0.247
Sfro	48688	0.058
Slon	16501	0.377
Ttro	15791	0.206
Ttrs	64897	0.177

The proportion exposed against the initial population size is shown here for the 15 taxonomic units

Injury metrics

In the following table we present the means of the 3 injury metrics:

Table 2: Injury results for the different stocks considered.

Sp	LCY	MPD	YTR
Bwsp	1321	-0.038	1.6
Fatt	1250	-0.042	2.3
Ggri	2449	-0.057	7.3
Gmac	1058	-0.035	1.2
Kosp	1429	-0.052	4.9
Pele	3072	-0.042	2.1
Pmac	2549	-0.064	9.7

Sp	LCY	MPD	YTR
Satt	33810	-0.035	0.6
Sbre	2434	-0.040	1.6
Scly	1902	-0.018	0.0
Scoe	3715	-0.059	7.1
Sfro	7509	-0.013	0.0
Slon	17715	-0.089	11.2
Ttro	11370	-0.057	6.6
Ttrs	35190	-0.042	2.4

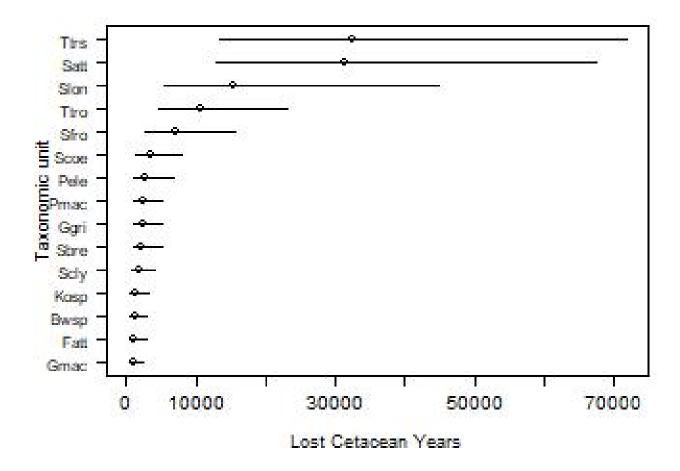

In the following table we present the medians and the 95% confidence intervals for our current estimates of injury. These correspond to the results in table 3 in the main paper.

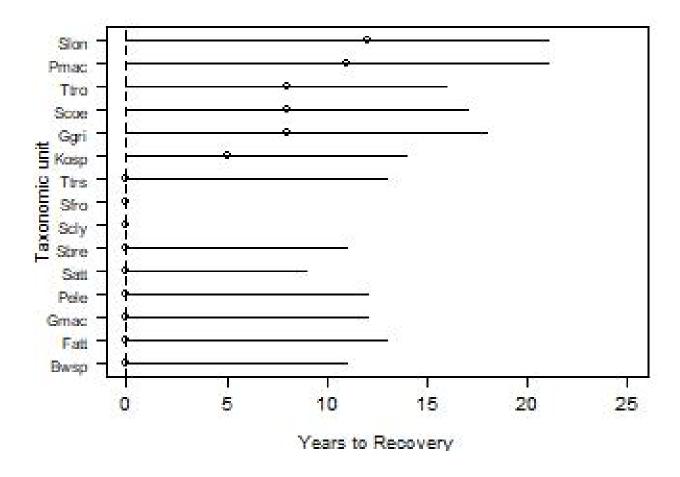

Table 3: Median injury results for the different stocks considered and respective 95% confidence intervals by the percentile method

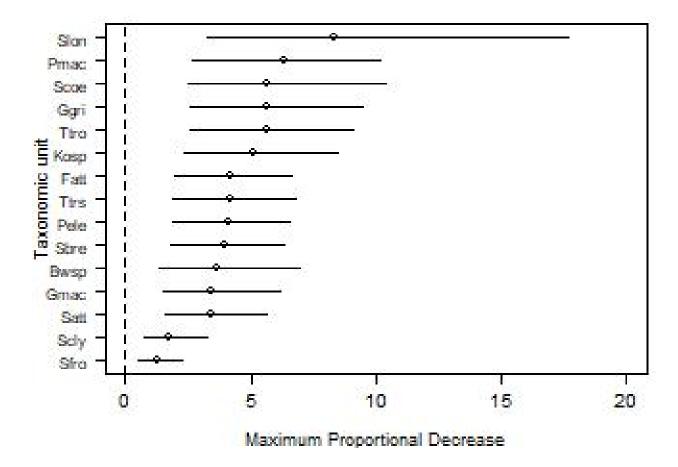

Sp	LCYmed	LCYl	LCYu	MPDmed	MPDl	MPDu	YTRmed	YTRl	YTRu
Bwsp	1207	445	2899	3.683	1.386	6.951	0	0	11
Fatt	1122	437	2809	4.186	1.939	6.642	0	0	13
Ggri	2264	978	5049	5.623	2.569	9.494	8	0	18
Gmac	964	385	2291	3.435	1.486	6.216	0	0	12
Kosp	1294	519	3112	5.114	2.315	8.492	5	0	14
Pele	2761	1081	6767	4.140	1.925	6.601	0	0	12
Pmac	2356	996	5240	6.344	2.672	10.189	11	0	21
Satt	31372	12884	67606	3.433	1.563	5.615	0	0	9
Sbre	2232	901	5207	3.995	1.836	6.349	0	0	11
Scly	1726	664	4067	1.734	0.747	3.261	0	0	0
Scoe	3387	1369	7897	5.673	2.479	10.426	8	0	17
Sfro	6961	2722	15509	1.264	0.542	2.280	0	0	0
Slon	15255	5302	44903	8.363	3.277	17.716	12	0	21
Ttro	10537	4597	23220	5.610	2.546	9.125	8	0	16
Ttrs	32584	13377	71967	4.152	1.859	6.758	0	0	13

These are the values that are used in table 3 of the paper, and the code to do so is in the .Rmd.

Representing the above information visually, focusing on each of the 3 injury metrics:

Exploring the injury metric results

In this section we explore the results obtained in terms of the different injury metrics and how these injury metrics might be explained by the different input parameters. To do so we consider generalized linear models to model the mean value of the injury per species as a function of the mean values of the input parameters. Only the following four parameters seem to have a considerable potential relevant effect on the injury metrics:

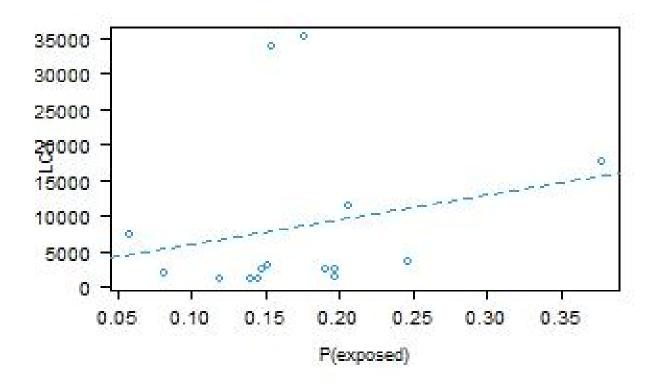

- Proportion Exposed
- Initial population size
- Gestation duration
- Survival reduction

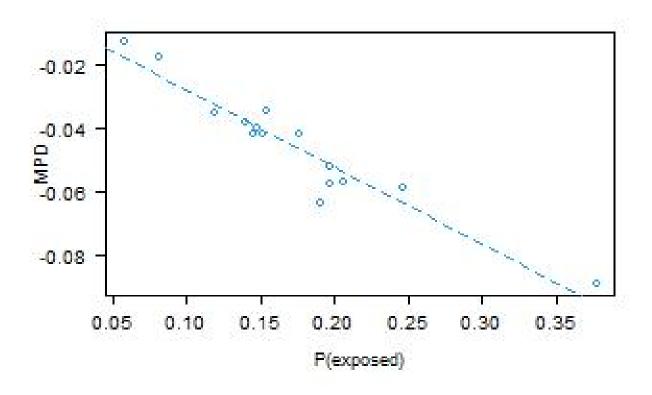

Exploratory analysis

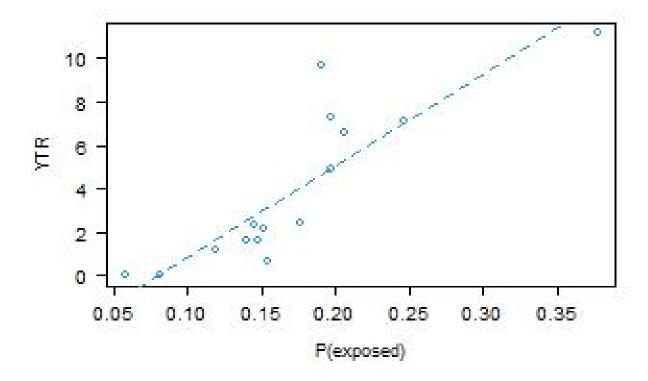

Here we plot the values of the injury metrics as a function of the four key parameters going into the model.

Proportion exposed

The next three plots describe the relationship between the proportion exposed and Lost Cetacean Years, the Maximum Proportion Decrease and the Years to recovery, respectively

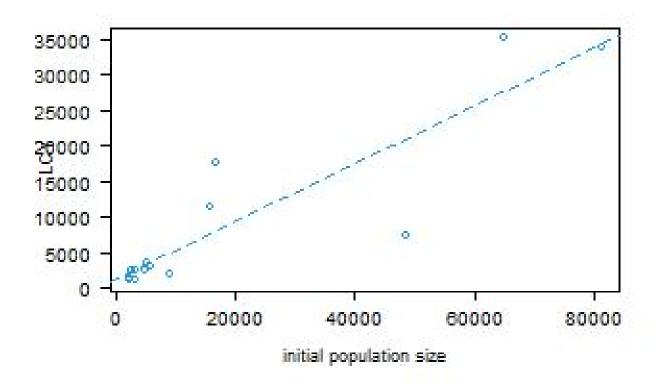

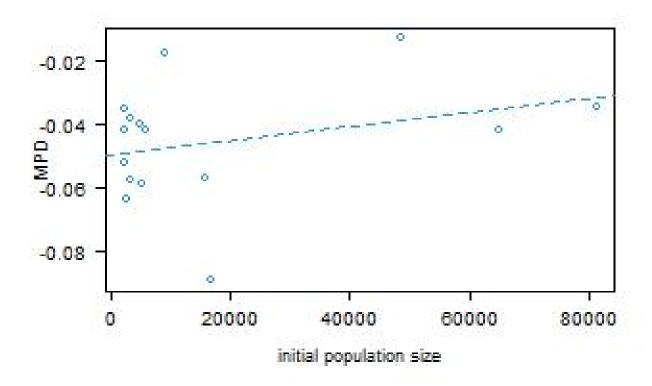

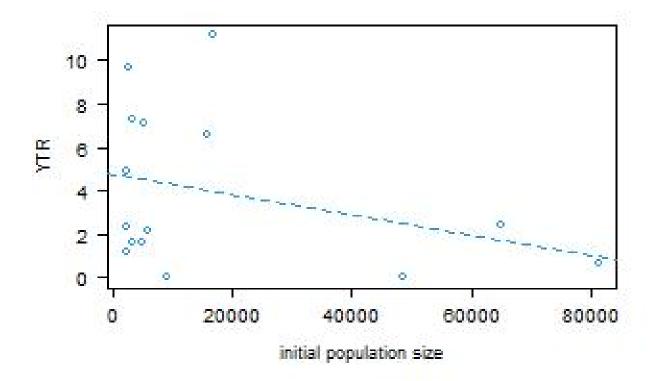

Initial population size

The next three plots describe the relationship between the initial population size and Lost Cetacean Years, the Maximum Proportion Decrease and the Years to recovery, respectively.

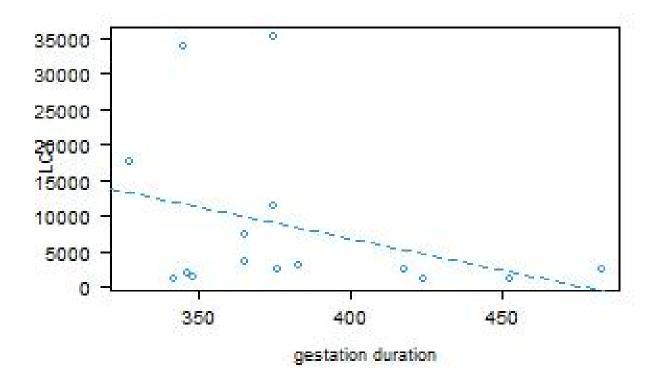

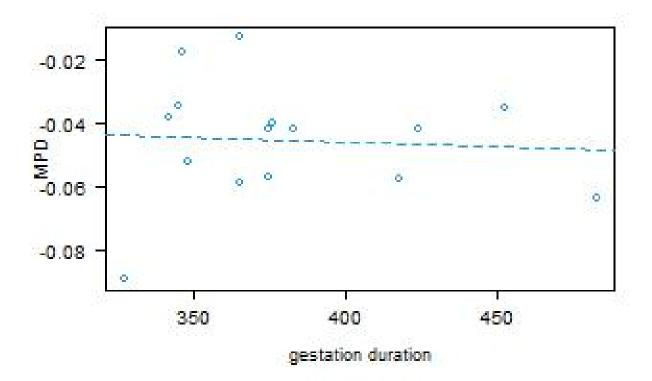

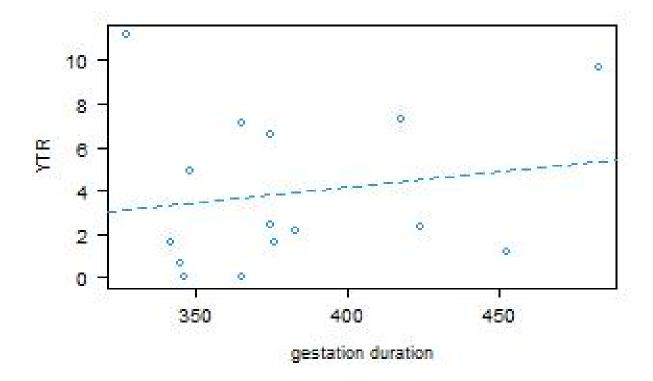

Gestation duration

The next three plots describe the relationship between the gestation duration and Lost Cetacean Years, the Maximum Proportion Decrease and the Years to recovery, respectively

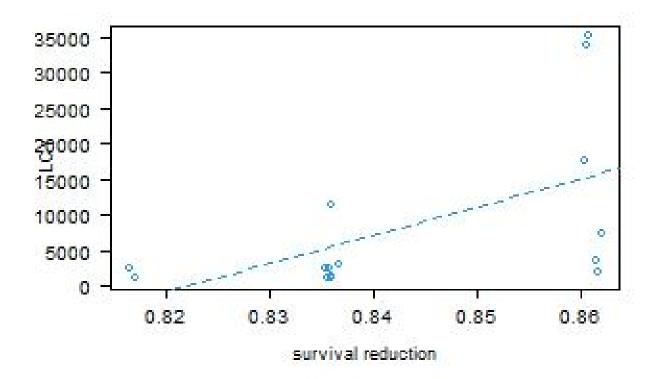

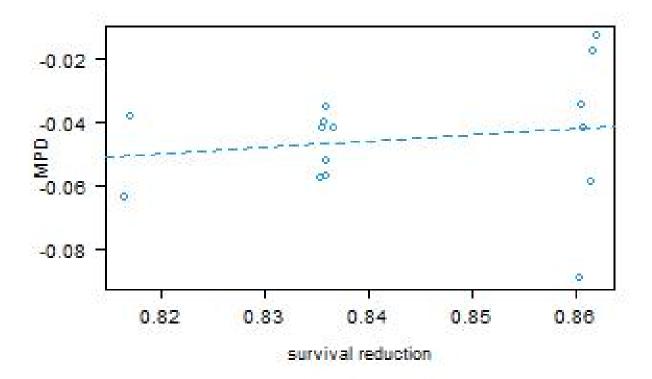

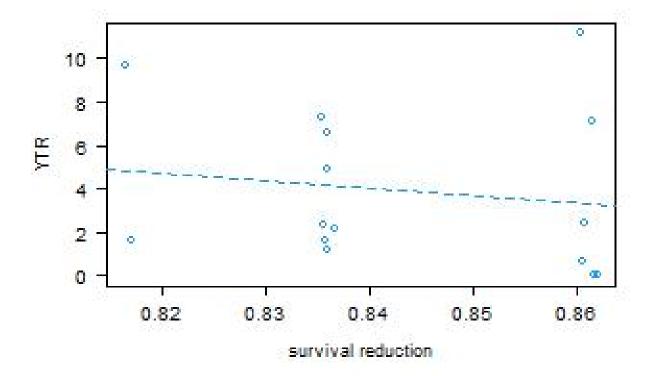

Survival reduction

The next three plots describe the relationship between the survival reduction and Lost Cetacean Years, the Maximum Proportion Decrease and the Years to recovery, respectively

Explaining injury metrics across species

Here we consider standard linear models to explain the injury metrics as a function of the input parameters.

LCY

As noted above, one can anticipate that LCY would be strongly dependent on the initial population size and the proportion exposed. Therefore, we fit a linear model, treating species as sampling units, to explain LCY as a function of these two quantities. The summary of the corresponding linear model follows. Then we present a plot representing the observed values of LCY and those obtained by predicting from fitting a linear model of LCY as explained by initial population size and the proportion exposed.

```

The LCY is very well explained by these two variable alone. A bit surprisingly, adding the gestation duration (that scales survival across species) does not even seem to help in explaining the injury

Using the most parsimonious model, the proportion of the variability explained by each input retained in the regression model and the remaining unexplained variation can be obtained from the ANOVA table of the linear regression. The proportion of variance explained in Lost Cetacean Years by the initial population size is 87.7 %, while the proportion exposed accounts for 4.94 %. Only 7.37 of the variability remains unexplained.

YTR

For YTR the following model describes which input parameters help explain the YTR

The proportion of variance explained in Years to Recovery by the proportion exposed is 73.89 %, while the gestation duration accounts for 11.13 %. About 14.98 % of the total variability remains unexplained.

MPD

The following model describes which input parameters help explain the MPD

```
##
## lm(formula = MPD ~ Pexp + Nstart + inputs$gd + inputs$sr, data = sumres)
##
## Residuals:
##
          Min
